Downregulation of lncRNA-HOXA11-AS modulates proliferation and stemness in Glioma cells

Zuoxin Zhang^{1,2,3}, Junhu Zhou^{1,2,3}, Junxia Zhang⁴, Ran Duan⁵, Peiyu Pu^{1,2,3} and Lei Han^{1,2,3*}

Abstract

Background: Glioma stem cells (GSCs) represent a subpopulation of cells within glioma that are characterized by chemotherapy resistance and tumor recurrence. GSCs are therefore important therapeutic target for glioma therapy. Long non-coding RNAs (lncRNAs) have been shown to regulate important functions in cancer. HOXA11-AS is one such lncRNA and has been shown to regulate cell proliferation via promotion of cell cycle progression in glioblastoma (GBM) cells. However, the specific roles of HOXA11-AS in GSCs remain unclear.

Methods: Here we investigated the role of HOXA11-AS in driving GSC stemness properties via sphere-forming and protein chip assays.

Results: Gain-of-function as well as loss-of-function results showed that the HOXA11-AS maybe a critical modulator in GBM recurrence as demonstrated by cell sphere-forming ability. Furthermore, we showed that induced expression of HOXA11-AS does increase the levels of stemness-related transcription factors (Oct4/Sox17/Sox2) in U87MG cells. In vivo xenograft experiments using the HOXA11-AS knockdown U87MG cells revealed that downregulation of HOXA11-AS could strongly inhibit tumor growth. Furthermore, we found that HOXA11-AS knockdown decreased the expression of cancer stemness markers in vivo.

Conclusions: Collectively, these data suggests that HOXA11-AS is involved in GSC stemness and supports its clinical significance as a important therapeutic target in glioma.

Keywords: Glioma, lncRNA, HOXA11-as, Glioma stem cells

Background

Glioblastoma (GBM) is the highest grade glioma (grade IV) in adults and remains incurable despite promising treatments for its heterogeneous features [1]. These phenotypes are thought primarily to be due to their derivation from glioma stem cells (GSCs), which are a highly tumorigenic and capable of self-renewal subpopulation of glioma cells [2]. As the self-renewing capability and multipotency may be closely associated with cancer progression and invasion, understanding the mechanisms underlying the regulation of stemness properties of glioma cells has been widely investigated.

Long non-coding RNAs (long ncRNAs, lncRNA) are a class of non-protein coding transcripts with a length longer than 200 nucleotides. Noncoding RNAs (ncRNA) may be transcribed from noncoding DNA, which represents over 98% of human genome DNA and is commonly referred to as “junk DNA” [3]. To date, studies have shown that lncRNAs affect the chromatin structure, mRNA stability and miRNA-mediated gene regulation by acting as competing endogenous RNA or natural miRNA sponges [4]. HOXA11 antisense (HOXA11-AS) was in 5-prime region of the HOXA locus. To date, only a few investigations have reported a association between HOXA11-AS and cancer. Richards et al. showed that HOXA11-AS could inhibit the proliferation and invasion of ovarian cancer via a series of functional assays [5]. Sun M et al. found that the 5' region of HOXA11-AS binds to chromatin-modifying complexes (PRC2 and

LSD1), hence inhibiting the transcription of its target genes (PRSS8 and KLF2) [6]. Our group has demonstrated that HOXA11-AS knockdown inhibits the cell cycle progression and proliferation of glioma cells [7]; however, the specific roles of HOXA11-AS in pluripotency regulation are still largely unknown.

Here, to explore the underlying molecular mechanisms of HOXA11-AS in the proliferation and stemness properties of GBM, we investigate the biological functions of HOXA11-AS in regulating the proliferation and maintenance of stemness by overexpression and knockdown of HOXA11-AS in U87MG cells in vitro and in vivo. Our observations show that HOXA11-AS is an effective modulator that regulates the glioma stem cell population.

Methods

Patients and samples

mRNA expression profile for glioma and normal tissues were got from the Chinese Glioma Genome Atlas (CGGA, <http://cgga.org.cn/>) [8]. Microarray analysis in 220 glioma cases (97 grade II, 34 grade III, and 89 GBM) and 5 normal brain samples was performed via the Agilent Array.

Cell culture and viral infection

Human GBM cell lines U87MG, LN229, U251 and human embryonic kidney 293 (HEK293) cells were purchased from ATCC (the American Type Culture Collection, Manassas, VA, USA). The U87-EGFRvIII cell line, which carries EGFR VIII mutation, was kindly provided by Prof. Ren of Harbin Medical University (Harbin, China) [9]. All GBM cell lines were routinely cultured at 37 °C in a 5% CO₂ humidified atmosphere in Dulbecco's-modified Eagle medium (DMEM) with 10% fetal bovine serum (FBS, HyClone). Lentivirus containing HOXA11-AS RNAi segments (the RNAi sequence is 5'-GCAGCAUGCUUGUGCUCAATT-3') and the luciferase reporter gene were obtained from Genepharma (Shanghai, China). Dox-inducible HOXA11-AS expression recombinant adenovirus was purchased from SinoGenoMax (Beijing, China). Doxycycline (dox) was purchased from Santa Cruz (Dallas, TX, USA). The GBM cell lines were infected with virus suspensions for 48 h according to the manufacturer's instructions.

Quantitative real-time PCR

Total RNA from glioma cells was extracted using TRIzol reagent (Life Technologies). The GoScript™ Reverse Transcription System (Promega, USA) can be used to synthesize the single stranded cDNA via reverse transcribing total RNA. To identify HOXA11-AS and GAPDH mRNA expression level, quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed using a CFX96 Real-Time PCR Detection

System (Bio-Rad Laboratories). The sequence of HOXA11-AS primer is as follows: Sense: 5'-CCCTCATCTTCCCTGCCTACCT-3', antisense: 3'-GGTTTCCC GAGTCCTCAGCT-5'.

Sphere formation assay

The sphere-forming assays were performed [10]. Briefly, cells (1×10^3 /well) were cultured in ultra low attachment 6-well plates in 2 mL of stem cell culture media and the media was supplemented with 2% B27, 20 ng/mL EGF and 20 ng/mL FGF-b on every other day. After 10 days, the cell spheres with a size larger than 50 μm were photographed and counted per well via microscope.

Analysis of stem cell marker by protein microarray

After infected by virus for 48 h, the U87MG cells were washed with PBS buffer and lysed with RIPA solution (Pierce, France) with the protease/phosphatase inhibitor cocktails (Sigma, USA). The expression of the human stem cell markers were analyzed by RayBio Human Stem Cell Array G1, none of the spots was under detectable fluorescence level and, therefore, we can calculate significance for all markers.

Nude mouse glioma intracranial model

Female Nu/Nu nude mice (aged 4–5 weeks) were purchased from the animal center at the cancer institute, Chinese Academy of Medical Science (Beijing, China). We infected U87MG cells with HOXA11-AS RNAi and luciferase lentivirus for 48 h. Then, we implanted stereotactically a total of 2.0×10^5 U87MG glioma cells into the brain of mice to establish intracranial xenografts model [11]. Each group has 13 mice. The fluorescent imaging of tumor progression in the orthotopic mouse model was monitored via the IVIS Lumina Imaging System (Xenogen, Waltham, MA, USA) every 7 days for three times. After 20 days of treatment, three mice per group were sacrificed and brains were collected and embedded in paraffin for immunohistochemical (IHC) staining. The remaining ten mice in each group were used for survival analysis.

Immunohistochemical analysis

For hematoxylin and eosin (HE) staining, the sections were placed in the distilled water before nucleus is stained with hematoxylin. Then, the sections were stained with eosin before being dehydrated and mounted. For IHC staining, the paraffin-embedded tissue sections were used for the examination the expression of Oct-4, and Sox-2. Sections were dewaxed, treated with H₂O₂, and then incubated with the primary antibodies (1:100; Santa Cruz Biotechnology) overnight at 4 °C, followed by incubation with biotinylated secondary antibody (1:100; Santa Cruz Biotechnology) for 1 h at room temperature. After

washing with PBS, the sections were incubated with 3,3'-diaminobenzidine (DAB) for approximately 1 min, and counterstained with hematoxylin.

Statistical analyses

The one-way analysis of variance (ANOVA), and *t*-test were used to determine statistically significant difference between different groups. Kaplan-Meier method analysis was used to assess the survival distributions, and the log-rank test was used to analyze the statistical significance. The cut-off point between high and low values for HOXA11-AS was its median values. Heat maps were generated via TreeView and clustering software. All data are presented as the mean ± standard error.

Results

Identification of HOXA11-AS in the mRNA microarray dataset

Since ncRNAs play a crucial role in cancer progression, we wanted to get the expression profile of ncRNAs in the CGGA database. Firstly, we combined the Agilent-028002 microarray dataset (1736 ncRNA probes), the lncRNA dataset (182 annotated lncRNAs) and the functional lncRNA dataset (172 annotated lncRNAs) to

obtain 1997 annotated noncoding RNAs. Secondly, we can further obtain 732 annotated ncRNAs within the CGGA dataset via overlapping the above 1997 ncRNAs with the 24,000 probes of the CGGA dataset (Fig. 1a). Thirdly, we further obtained the differential expressed ncRNAs (SAM: Fold change >1.5, Q value <1%) among the glioma samples in different grade via SAM analysis. Lastly, we obtained the expression profile of several tumorigenesis-related ncRNAs, which revealed the increased or reduced expression upon glioma grade. Among these ncRNAs, we focus on a novel lncRNA HOXA11-AS for its unknown function in glioma (Fig. 1b).

HOXA11-AS regulates stemness qualities of GBM cell

To further investigate the effect of HOXA11-AS on stemness characteristics, the expression level of HOXA11-AS in HEK293, U87MG, U87vIII, U251 and LN229 cell lines was firstly measured via qPCR. The expression level of HOXA11-AS in HEK293 cells was used as a control. The results showed that the expression level of HOXA11-AS in U87MG and U87vIII cells was lower than that in LN229 and U251 cells (Fig. 2a). It has been demonstrated that EGFRvIII could promote self-renewal and tumor progression of glioma stem cells [12]. However, we found that

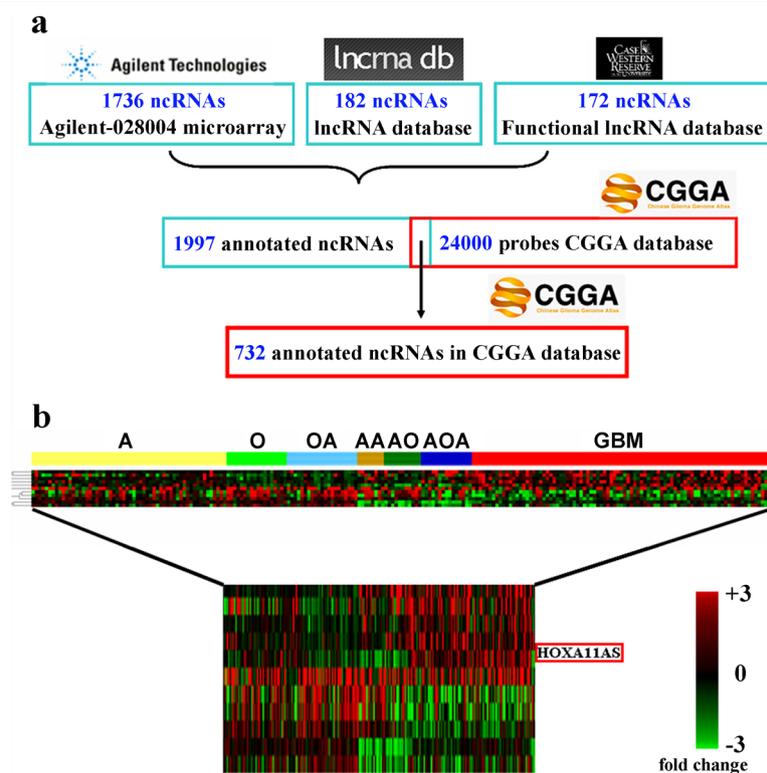

Fig. 1 NcRNA expression signature in the CGGA database and evidence that the novel lncRNA- HOXA11-AS confers poor prognosis in glioma patients. **a** Non-coding RNAs were obtained from CGGA, the lncRNA database and the functional lncRNA database. **b** Sum analysis of the correlation of glioma grade with its associated lncRNAs in CGGA database

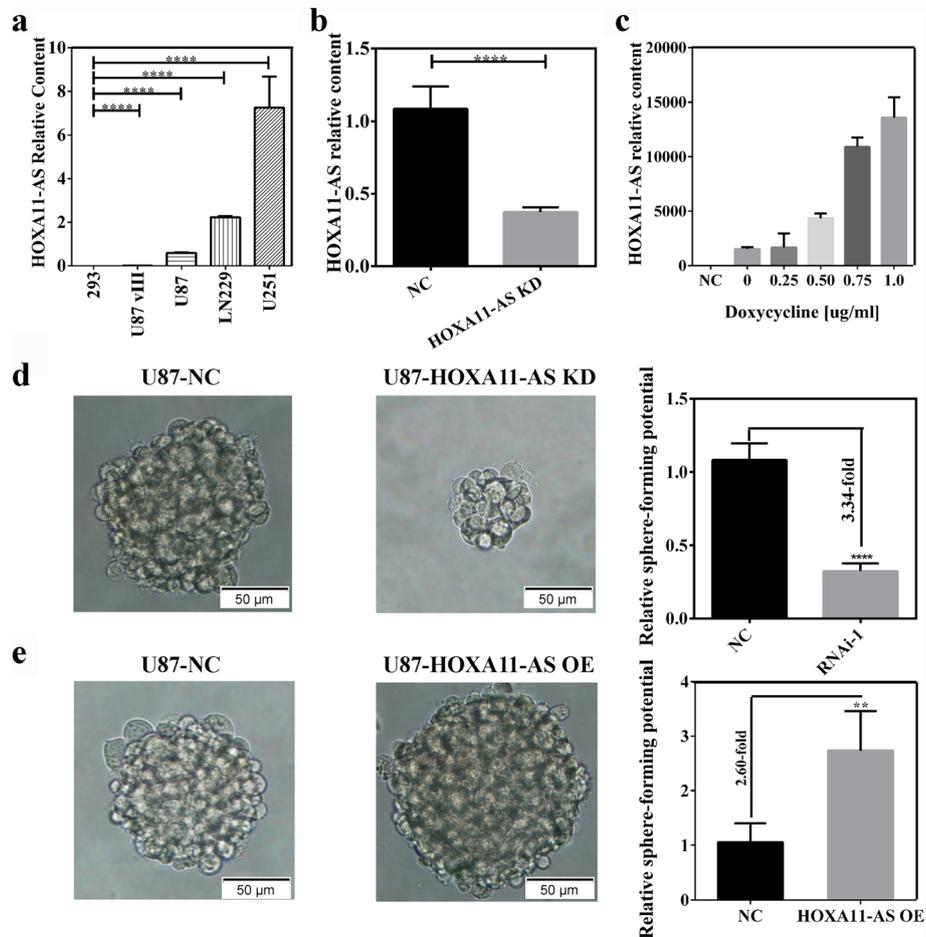

Fig. 2 HOXA11-AS regulates glioma stemness in vitro. **a** mRNA expression of HOXA11-AS genes was determined in GBM cell lines and normal epithelial cell cultures by qRT-PCR. Expression levels are shown relative to the expression in HEK293 cells, which was used as a control and set as 1. **b** qRT-PCR was used to detect HOXA11-AS expression of U87MG cells with lenti-HOXA11-AS knockdown. **c** qPCR panels represent HOXA11-AS expression in U87MG cells infected with lentivirus-HOXA11-AS overexpression and incubated with different concentrations of doxycyclin (dox) in the culture medium for 2 days. **d** and **e** HOXA11-AS expressing or silenced U87MG cells (1×10^3) were seeded in ultra-low attachment plate and allowed to grow for 10 days in stem cell culture medium. Images were taken under light microscope and the number of spheres (size $>50 \mu\text{m}$) was counted. (** $p < 0.01$; **** $p < 0.0001$)

the expression of HOXA11-AS was the lowest in U87vIII cell lines among the four GBM cell lines, which maybe due to the EGFR antagonism in U87vIII cell lines [13].

To address whether HOXA11-AS could regulate stemness characteristics in glioma cells, HOXA11-AS were overexpressed or knockdown in U87MG cells via adenovirus or lentivirus infection, respectively. It was shown that HOXA11-AS RNAi virus could significantly decrease the expression of HOXA11-AS in U87MG cells compared with control (Fig. 2a), while rAd-HOXA11-AS virus could also significantly increase the expression of HOXA11-AS in U87MG cells compared with the control (Fig. 2c). Next, we characterized the stemness qualities of the U87MG cells in vitro via the sphere-forming assay. HOXA11-AS knockdown could impair its sphere-forming ability (Fig.

2d), while HOXA11-AS overexpression could promote the sphere formation of U87MG cells than that in control group (Fig. 2e).

HOXA11-AS has a marked effect on the stemness of GBM cells

To determine molecular stemness mechanisms of HOXA11-AS, we detected associations between the expression levels of HOXA11-AS and stem cell markers in CGGA cohort, suggesting that HOXA11-AS expression was positively related to expression of BMX, CD15, CD133, EZH2, GATA4, nestin, and PDX1. Furthermore, we further performed protein chips using protein lysates obtained from U87MG cell lines treated with HOXA11-AS overexpression adenovirus, or control adenovirus for

48 h. We found that the HOXA11-AS overexpression in U87MG cells resulted in increasing stem cell markers expression (Oct-4, Sox2, and Sox17 et al.) (Fig. 3b and c).

HOXA11-AS promotes glioma progression in vivo

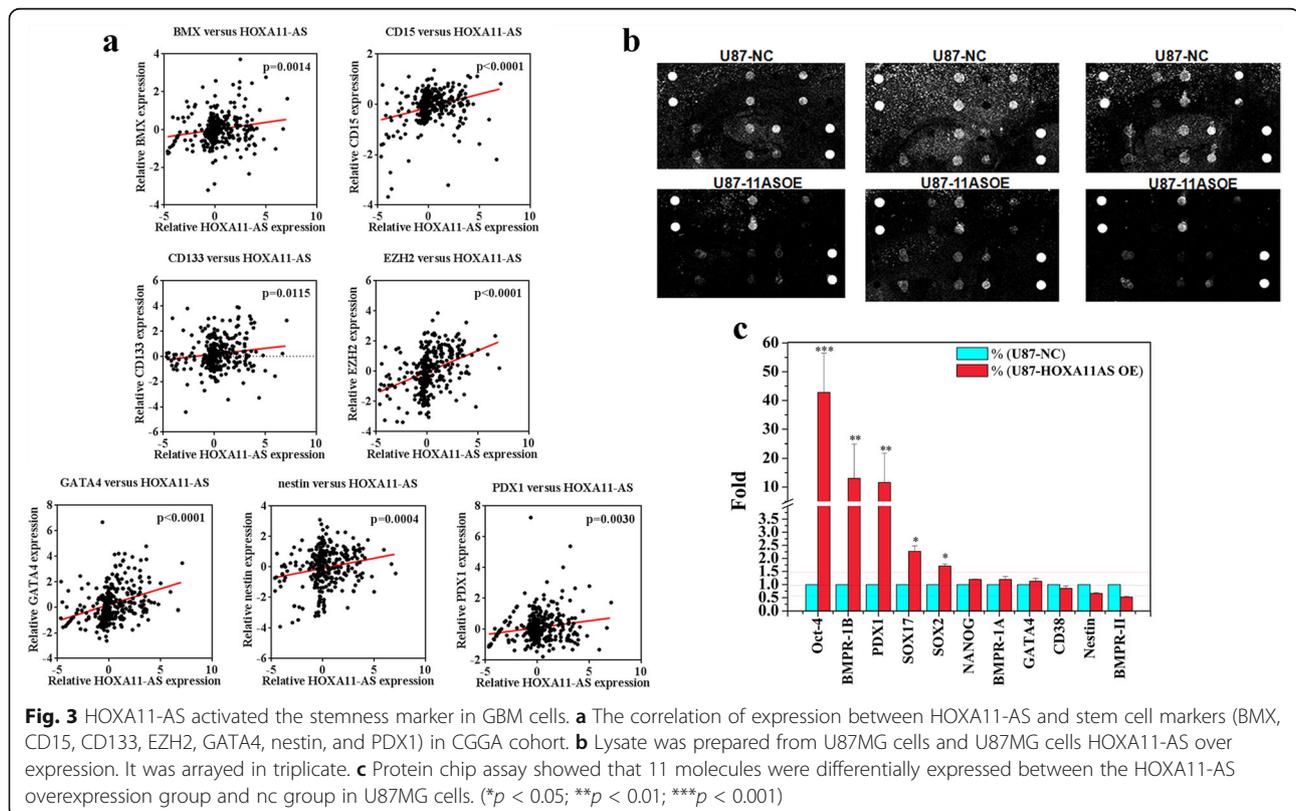

To investigate the effect of HOXA11-AS on proliferation and stemness in vivo, the U87MG cell lines with knock-down of HOXA11-AS were orthotopically injected into brain of nude mice. To monitor treatment responses in vivo, U87MG cells were infected with lentivirus to stably express firefly luciferase prior to intracranial implantation. It was shown that HOXA11-AS knockdown could resist the progression of U87MG cells in vivo (Fig. 4a and b). The survival time of mice in HOXA11-AS knockdown group was prolonged compared with that in control group (Fig. 4c). HE staining of xenograft brain samples further demonstrated that the ratio of tumor growth resisted in the HOXA11-AS knockdown group compared with that of the control group. The stemness marker (Oct-4, Sox-2) were obviously lower in HOXA11-AS knockdown group compared with that in control group (Fig. 4d). In a word, these results showed that HOXA11-AS could enhance glioma proliferation and stemness in vivo.

Discussion

GBM is the most common and deadliest of malignant primary brain tumor. Even after current standard treatment

with successful surgical resection, combination of radiotherapy with chemotherapy (temozolomide), GBM are associated with a poor prognosis due to chemotherapy resistance and histopathological heterogeneity [14]. Gliomas contain relatively undifferentiated cells called GSCs, which are associated with gliomagenesis, therapeutic resistance, and inevitable recurrence [15]. Therefore, to explore the underlying molecular mechanisms of stemness properties of GSCs would have great clinical implications for better treatment of glioma. In this research, for the first time, we investigated the effect of HOXA11-AS on the stemness characteristics in glioma via detecting the expression of stemness-related markers, and sphere-forming ability.

Enhanced sphere-forming ability and resistance to treatment (chemotherapy and radiotherapy) are the two common properties of CSCs. As we all know, the treatment resistance is mainly attributed to self-renewing capacity of CSCs in the minority subpopulation of cancer cells. Previous studies have demonstrated that GSCs enhance the chemo-resistance of glioma to TMZ. In this work, in vivo as well as in vitro results showed that HOXA11-AS knockdown not only decreased the expression of stemness markers in protein level, but also dramatically impaired the sphere-forming ability of GBM cells. We also noticed the enhanced expression of stemness-related markers (including Oct4, Sox2, Sox17, and Nanog) in HOXA11-AS overexpressed GBM cells

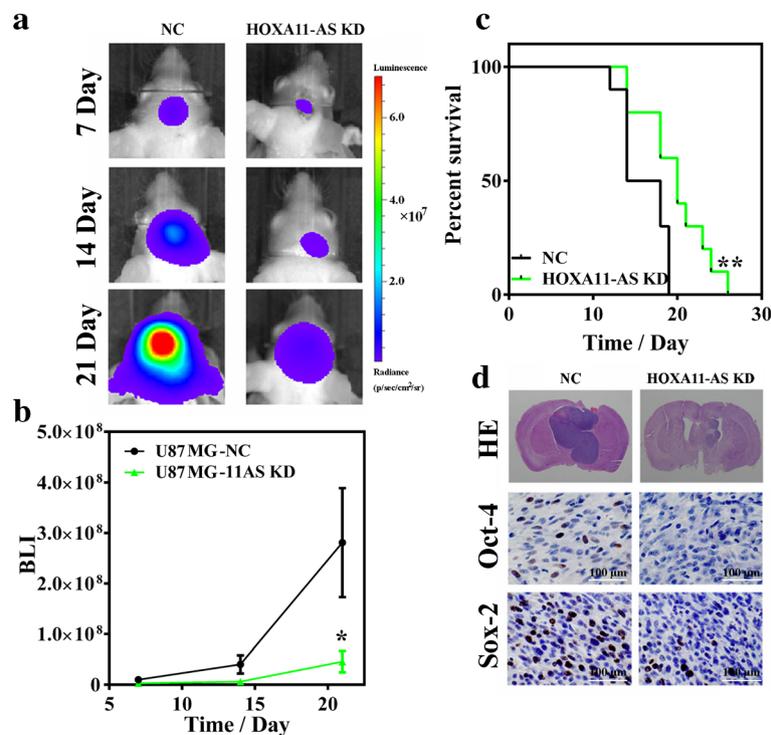

Fig. 4 HOXA11-AS expression associated with tumor growth rate and stemness markers in an intracranial glioma murine xenograft model **(a)** U87MG cells pretreated with a lentivirus with HOXA11 RNAi, or NC and lentivirus containing luciferase were implanted into the brains of nude mice, and tumor formation was assessed by bioluminescence imaging. Changes in bioluminescent signal were detected at days 7, 14, and 21 day after implantation. **b** Bioluminescence (BLI) was monitored to assess the tumor growth at days 7, 14, and 21. **c** Overall survival was determined by Kaplan-Meier survival curves and log-rank test was used to assess the statistical significance of the differences. **d** Tissue slices were stained with Hematoxylin-eosin-saffron. Representative images of immunohistochemical staining for Oct-4, and Sox-2. (* $p < 0.05$; ** $p < 0.01$)

via protein microarray. Previous studies have demonstrated that the Oct4, Sox2, Sox17, and Nanog are the important regulator of stemness in the different types of cancer including GBM [16, 17]. In summary, our findings further indicate that HOXA11-AS maybe involve in maintenance of stemness in glioma.

Conclusions

This study demonstrates that lncRNAs HOXA11-AS are involved in regulating the stemness of glioma cells. As discussed above, HOXA11-AS could be significant for not only targeting therapy to the bulk glioma cells, but also affecting the stemness of glioma. Therefore, selective inhibition of HOXA11-AS activity in glioma should provide new opportunities for the glioma therapy.
